Spatial Patterns and PFOA in Groundwater (2016-Present) Temporal Trends

Tim Schroeder & David Bond (Faculty)

Kasha Butterfield, Peace Kalomba, August
Schnell, & Alejandra Vouga (Students)

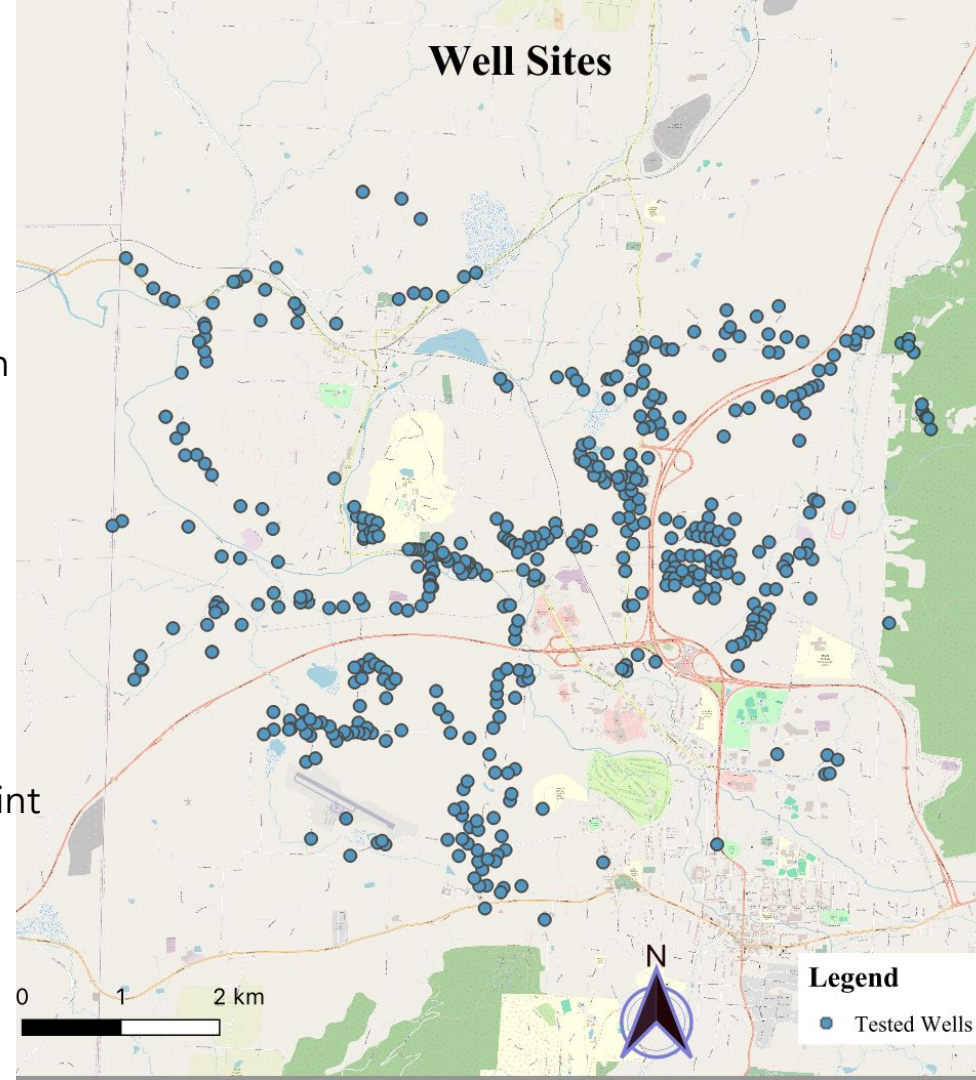

PFOA Dataset Overview

(data from VT DEC)

- PFOA data from ongoing monitoring of private wells around Bennington (2016 to present).
- Over 6,000 samples from Bennington Region in dataset.

Bennington College analysis:

- We cleaned up full dataset.
- We only considered samples from raw water or POET Influent (unfiltered groundwater).
- We did not include samples from POET Midpoint and POET Effluent (drinking water post-GAC filter).
- We analyzed 4,797 samples from 698 unique wells in Bennington Region.

DATASET: Compiled all data on PFOA levels in wells (and calculated average PFOA level in each well) and GPS coordinates for each well.

ANALYZED our dataset for:

1. Spatial Patterns
2. Temporal Trends

VERMONT

Drinking Water Standard (PFOA):

20 ppt

FEDERAL (EPA)

Drinking Water Standard (PFOA):

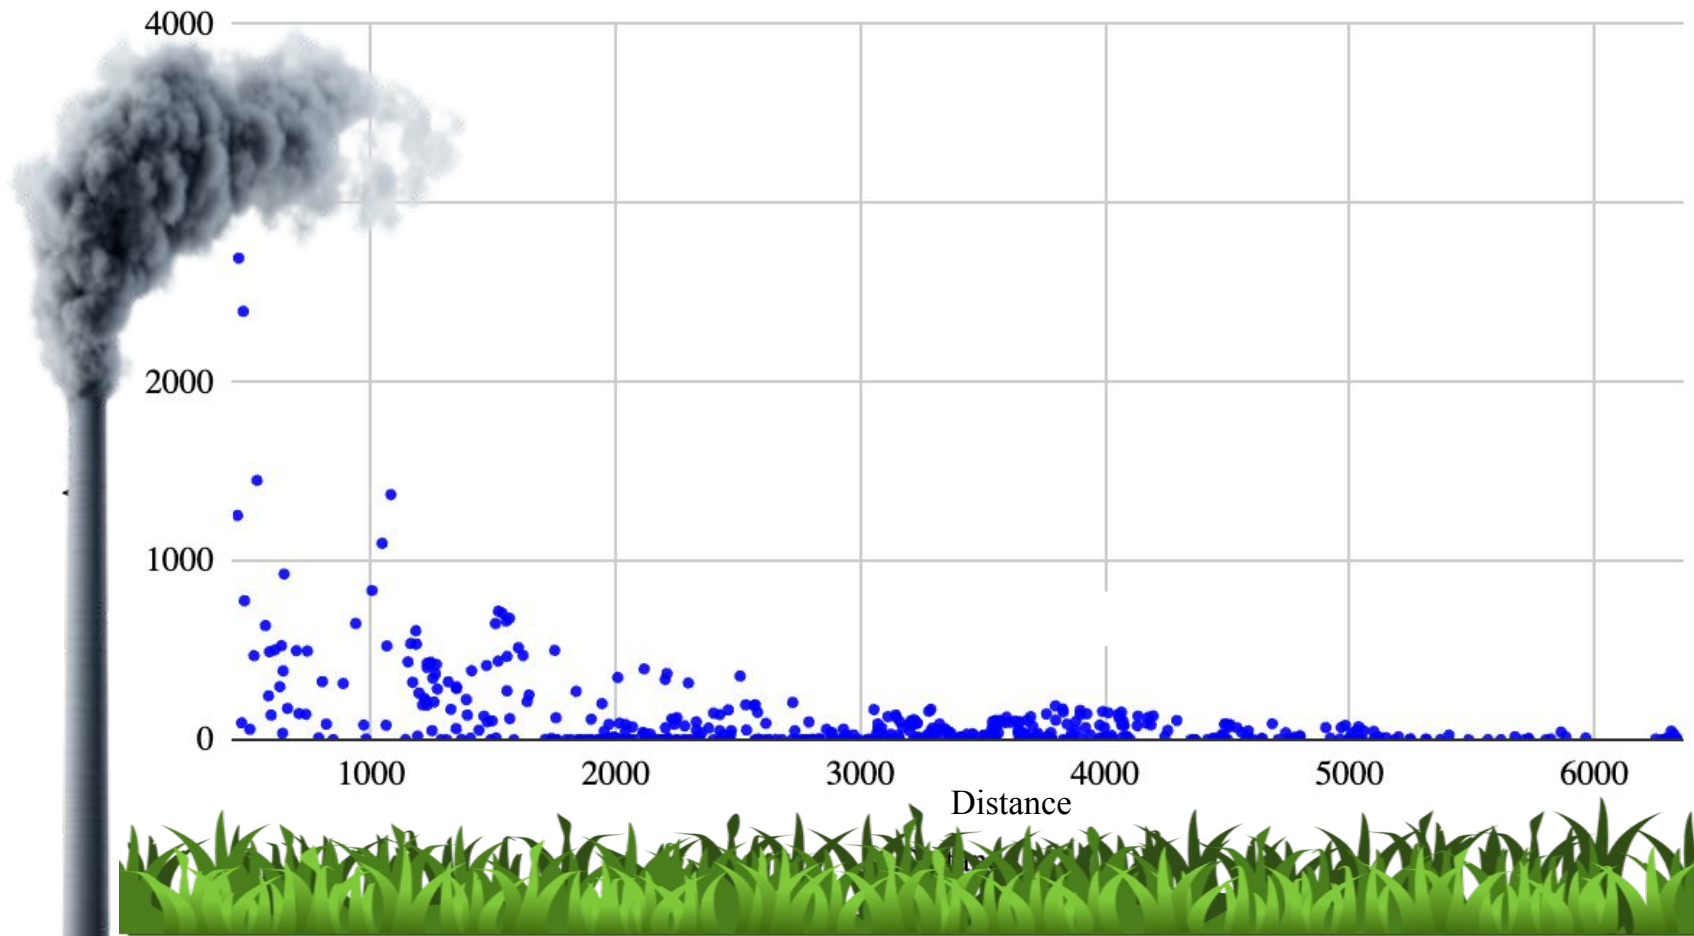

4 ppt

Northwest to the
Southeast

Are some bedrock formations more contaminated than others?

- To analyze the patterns of the PFOA levels with the bedrock formations we did an overlay analysis of the wells with the bedrock geologic map layer in QGIS software
- Intersected the wells and the bedrock formations
- Statistical analysis: ANOVA and Tukey Pairwise Test

Bennington Bedrock Map

Lithocodes:

- Oww - Whipstock Breccia Member
- Owu - Quartzose and Siltstone Phyllite, Chert horizons in the Whipstock Breccia
- Owbl - Black Slate and Gray to Blue Chert Member
- Ow - Walloomsac Formation
- Os - Shelburne Formation
- Ob - Bascom Formation
- Cw - Winooski Formation
- Csp - Clarendon Springs Formation
- Cm - Monkton Formation
- Cdu - Dunham Formation
- Cc - Cheshire Formation

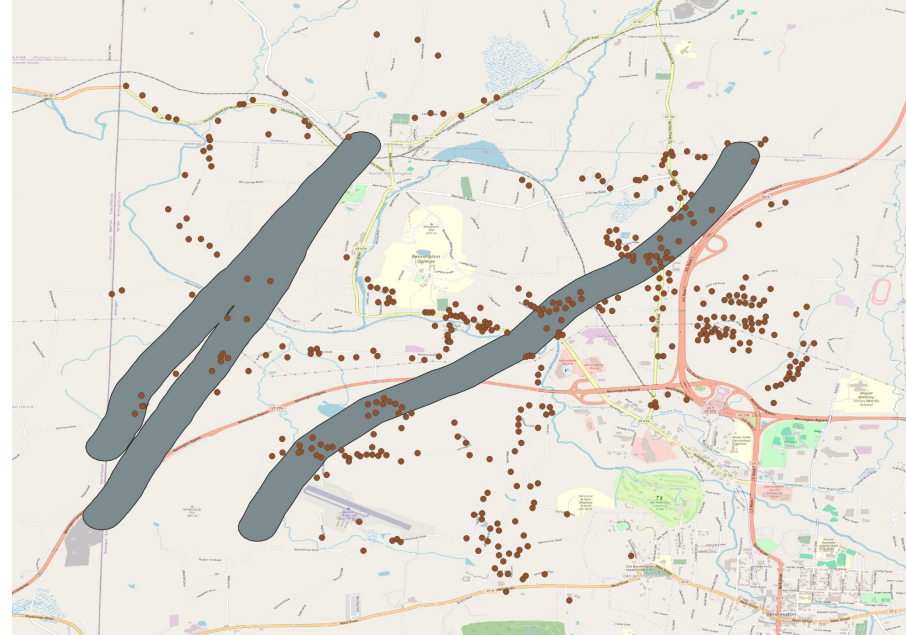

Distribution of Average PFOA Levels by Bedrock Type

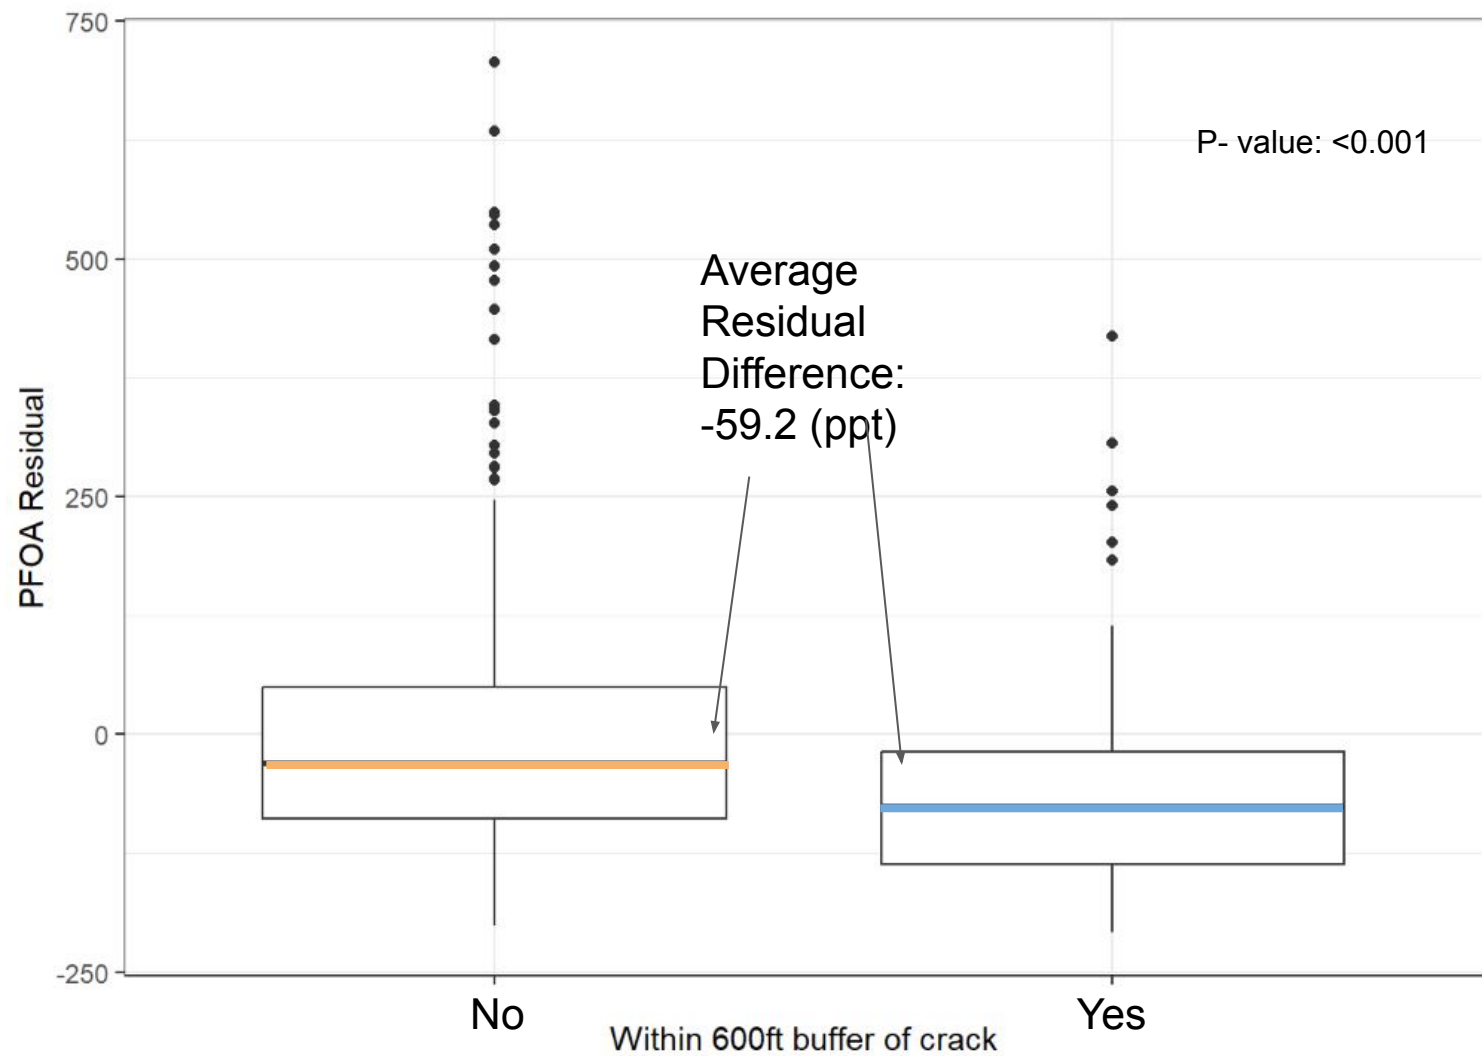

Are major bedrock faults a conduit for PFOA?

Qs: Do wells that fall in the bedrock fault areas have a statistically significant difference in PFOA levels.

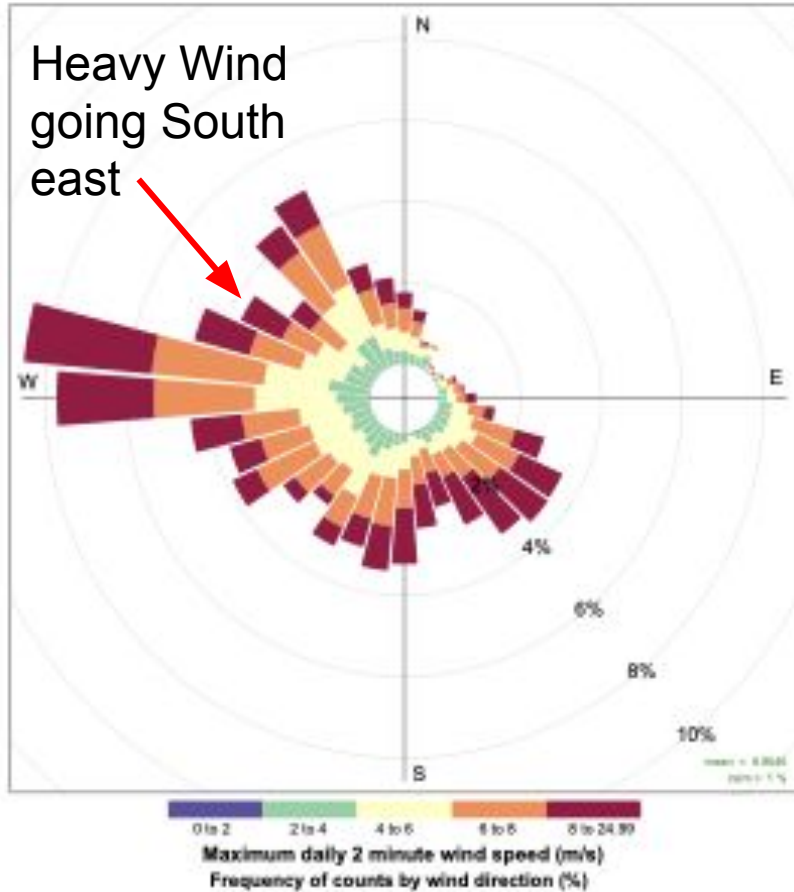

Ans: Yes, there is a statistically significant difference, with wells not on the bedrock faults having higher than expected PFOA levels.

Wind Direction and PFOA levels

- Found compass direction from ChemFab to each well
- Sorted them into 30 degree bins and calculated average PFOA levels.
- Made two polar histograms:
 - One with all PFOA wells
 - One with wells exceeding 200 ppt removed

PFOA lvs in
ts per trillion
ot) for wells in
t direction

200 ppt cut off

PFOA levels in relation to land slope direction

Slope-Aspect analysis in GIS

- Wells divided up east and west of ChemFab
- On the east; slopes with an aspect of 0-180 face toward ChemFab, 180-360 face away from ChemFab
- On the west; slopes with an aspect of 0-180 face away from ChemFab, 180-360 faces toward ChemFab
- No statistically significant results for both analyses

- Facing away from ChemFab

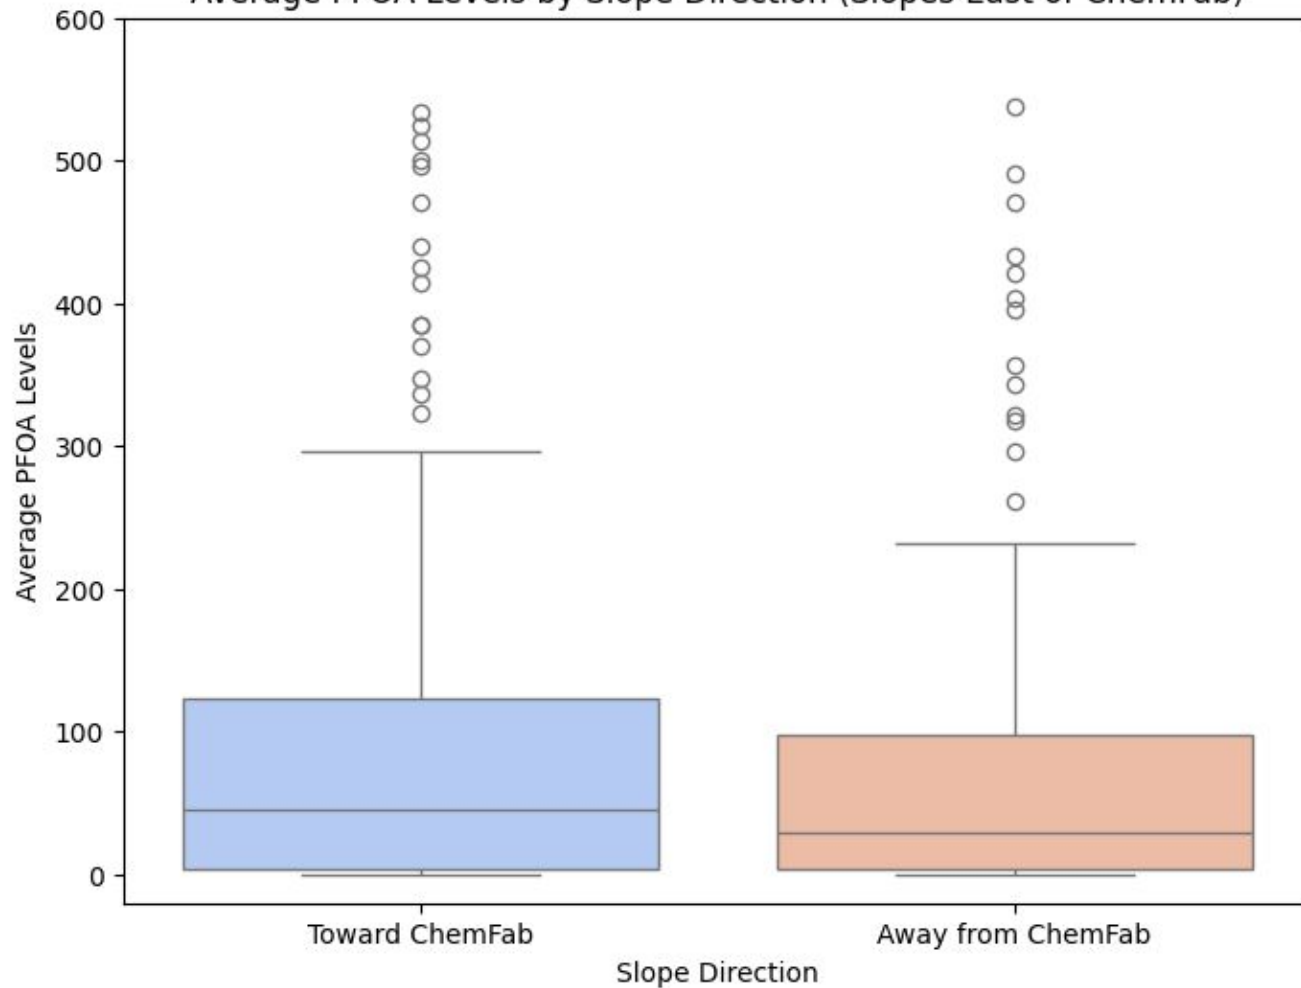

- Facing Towards ChemFab

 ChemFab

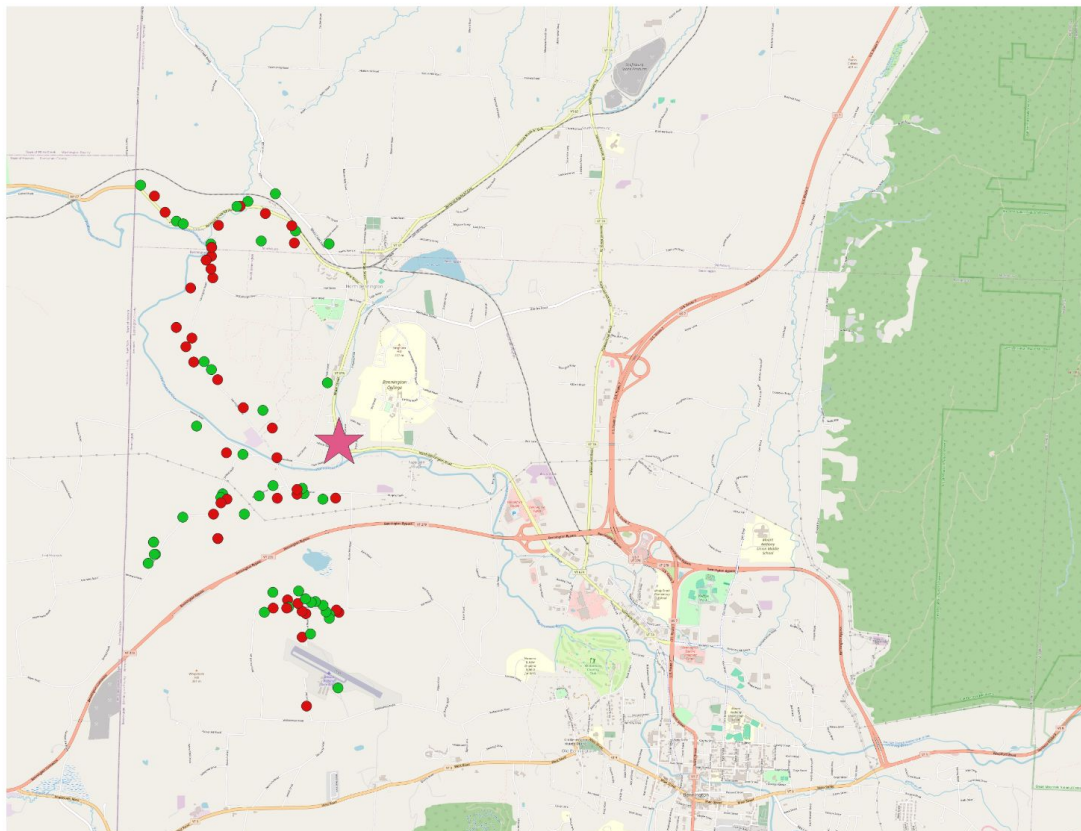

0 750 1,500 m

Average PFOA Levels by Slope Direction (Slopes East of ChemFab)

Map Showing Slope Direction (West of ChemFab)

★ ChemFab

0 1,000 2,000 m

Average PFOA Levels by Slope Direction (Slopes West of ChemFab)

Average PFOA Levels by General Slope Direction

2. Temporal Trends

Temporal Analysis

- Goal: Determine if there is trend of increasing or decreasing PFOA concentration
- Null Hypothesis (& what I expected): There will be no temporal trend visible in the data
- Performed a time-series linear regression on analyses from individual wells
- Only considered wells with >500 days time gap between initial and final sampling, AND the average PFOA concentration for all samples is > 2 ppt
- This comprises 323 wells/sites

Results:

Example of a site with an decreasing concentration trend

Results:

Example of a site with an increasing concentration trend

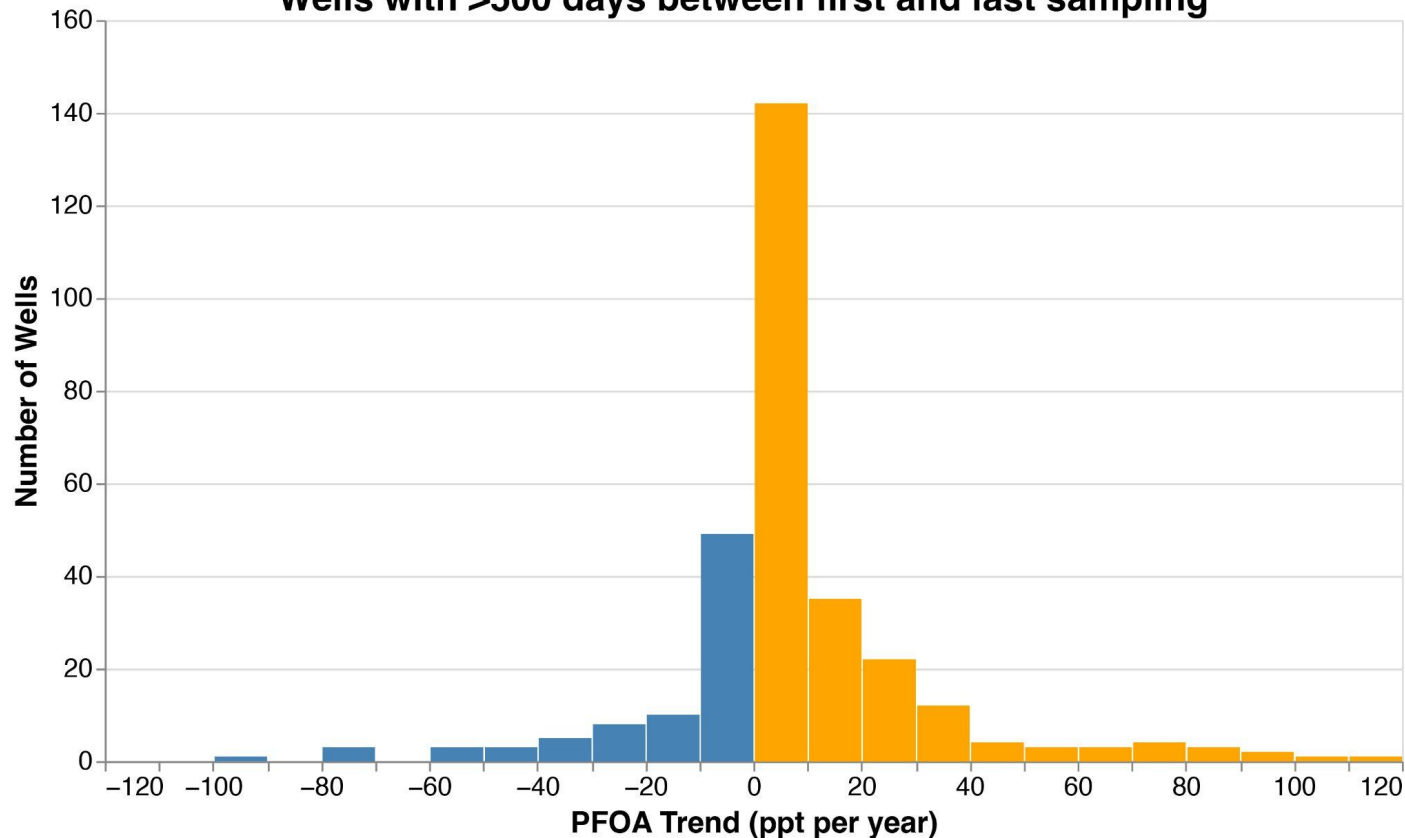

Results:

Example of a site with an increasing concentration trend, and from which this initial samples was ND

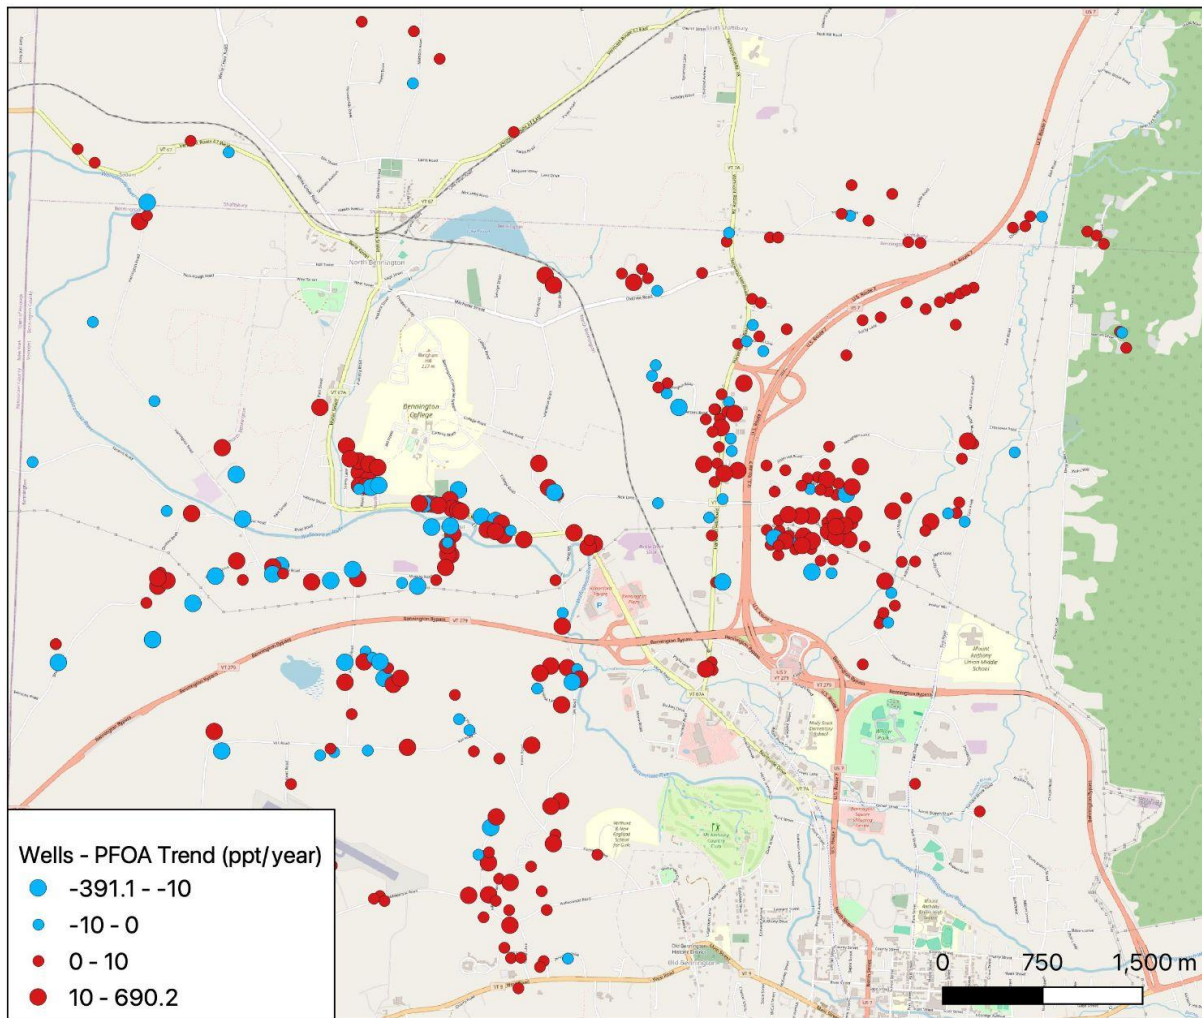

Putting it all together:

Wells with >500 days between first and last sampling

Histogram is clearly skewed toward positive slope (i.e. increasing PFOA trend)

239 increasing
84 decreasing

Is there a spatial pattern in the temporal trend?

Conclusions

- Results are consistent with earlier work indicating that PFOA was dominantly spread by air emission
- Secondary controls based on local topography and variability in bedrock aquifer flow patterns
- Temporal analysis indicates that PFOA levels continue to rise across the region
- Monitoring should continue across the region
